

Drone technology accurately maps rangeland condition of dry savannahs

Vistorina Amputu*, N. Knox, A. Braun, S. Heshmati and K. Tielbörger

1

Global changes → loss of biodiversity

• Drylands

- Structurally and functionally diverse
- Compromised by ‘unwanted’ shifts

Amputu et al. – Mapping dryland savannahs using drone technology

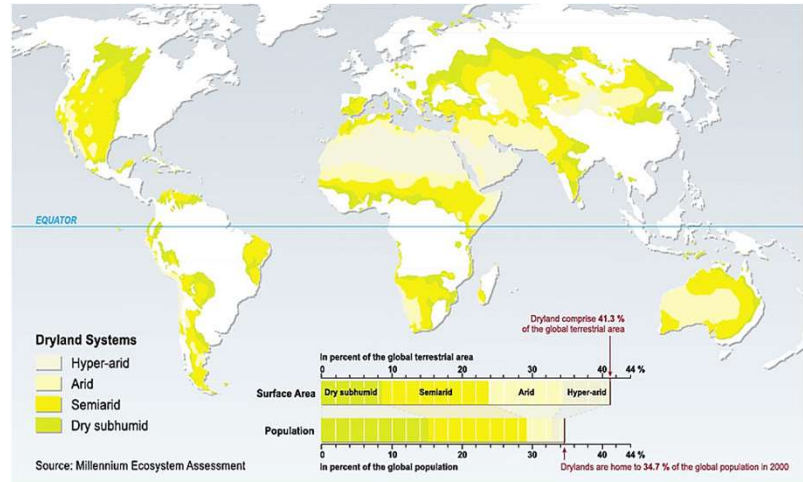

2

2

Global changes → loss of biodiversity

• Drylands

- Structurally and functionally diverse
- Compromised by 'unwanted' shifts

3

3

Monitoring biodiversity

• Cost-effective monitoring

- Easy with repeatable results
- Multiple spatial & temporal scales

• Drone technology

- Complementary tool in ecological research.
- Limited application in arid savannas

- **Aim:** validate drone-based mapping of rangeland condition with field data.

- **Hypotheses**

1. Significant positive relationship between drone-estimated and field **land cover**.
2. Significant positive relationship between **forage biomass** predicted from drone imagery and measured in field.

14

What we found

Amputu et al. – Mapping dryland savannas using drone technology

15

15

Strong agreement between drone-estimated and field land cover

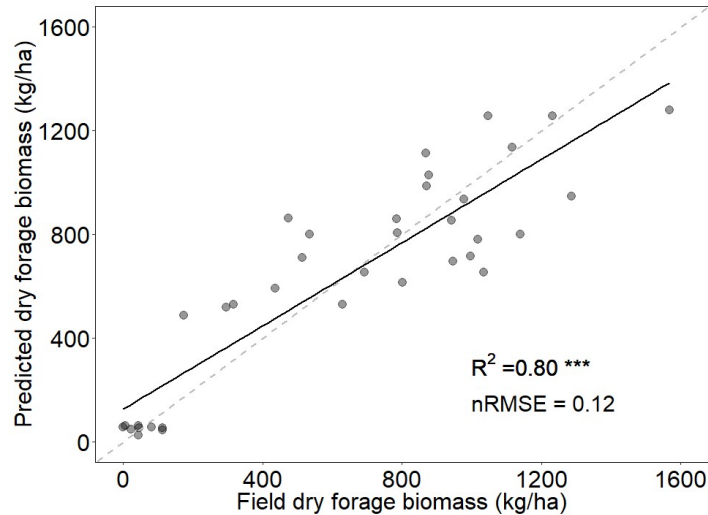

Amputu et al. – Mapping dryland savannas using drone technology

16

16

Strong agreement between drone-estimated and field forage biomass

Amputu et al. – Mapping dryland savannahs using drone technology

17

17

Take home message

1. **Consensus** between drone and field estimates of land cover & forage biomass
2. Drone-based prediction models can be used for **landscape-level** monitoring
3. Improve climate-adapted rangeland management and ecological research

18

18

Outlook: Next chapter

- Drone-based indicators of land degradation: a space-for-time approach

19

Outlook: Collaboration

- Upscale **forage quality and quantity** from field hyperspectral data to drone imagery for landscape monitoring
